Abstract

Results are presented for GeoPT15, round fifteen of the GeoPT international proficiency testing programme for analytical geochemistry laboratories. The sample distributed for this round was MSAN, an ocean floor sediment sample collected and prepared as a candidate reference material by the National Research Centre for Geoanalysis, Beijing, P.R. China. In this report, contributed data are listed, together with an assessment of assigned values, z-scores and charts showing both the distribution of contributed results and the overall performance of participating laboratories.

Introduction

This fifteenth round of the international proficiency testing programme, GeoPT15, was conducted in a similar manner to earlier rounds. The programme is designed to be part of the routine quality assurance scheme of analytical geochemistry laboratories. The trial involves distributing a sample of established homogeneity to participating laboratories, which are required to analyse the sample using a well-characterised technique or techniques operated under routine analytical conditions. Results are then tabulated by the organisers and z-scores calculated by comparing each analysed result submitted with the value assigned to be the best estimate of the true composition. These assigned values were estimated by robust statistical analysis of all the contributed data. By examining the magnitude of the z-score, participating laboratories can decide whether the quality of their data is satisfactory in relation to both their chosen fitness-for-purpose criterion and results submitted by all the other laboratories contributing to the round, and choose to take corrective action if this appears justified.

Full details of the programme have been included in reports of previous rounds, the current publication status of which is listed in Appendix 1. More specifically, the procedures followed in this round comply with the protocol published for conducting the GeoPT series of proficiency tests (see www.geoanalyst.org). In this report, therefore, only the features of the present round are included and readers interested in further details are invited to review the GeoPT protocol and previously published reports.

Steering Committee for Round 14: M. Thompson (Chair), P.J. Potts (Secretary), S.R.N. Chenery, P.C. Webb and WANG Yimin.

Sample: The Ocean floor sediment sample (MSAN) used in GeoPT15 was collected and prepared as a candidate reference material by the National Research Centre for Geoanalysis, Beijing, P.R.China, under the direction of Prof WANG Yimin.

The sample was tested for homogeneity by selecting at random ten packets of the material that had been prepared for distribution. Duplicate test portions from each packet were analysed by WD-XRF at the OU. For the elements that were assigned values, homogeneity was considered to be satisfactory for use in the GeoPT15 round. An analysis of the homogeneity results with additional comments is listed in Appendix 2.

Timetable for GeoPT14:

Distribution of sample: March 2004.
Deadline for submission of analytical results: 15th May 2003.
Distribution of draft report: June 2004

Submission of results

Results submitted by the seventy-nine laboratories that participated in this round are listed in Table 1. All these data (except P79 - late submission) were used for the assessment of assigned values.

Assigned values

Following procedures described in earlier rounds, a robust statistical procedure was used to derive assigned concentration values [X_a], these being judged to be the best estimates of the true composition of this sample. Data in Table 2 lists assigned values for 10 major and 43 trace elements. Values were assigned on the basis that: (i) sufficient laboratories had contributed data for an element, (ii) the statistical assessment gave confidence that the results showed a central portion approximating to a normal distribution. Part of this assessment involved examining a bar chart for each element to judge the distribution of results. Bar charts for elements/species shown in Figure 1 were judged to have satisfactory distributions, namely:

SiO_2, TiO_2, Al_2O_3, Fe_2O_3T, MnO, MgO, CaO, Na_2O, K_2O, P_2O_5, As, Ba, Be, Br, Cd, Ce, Co, Cr, Cs, Cu, Dy, Er, Eu, Ga, Gd, Hf, Ho, La, Li, Lu, Mo, Nb, Nd, Ni, Pb, Pr, Rb, Sb, Sc, Sm, Sn, Sr, Ta, Tb, Th, Tl, Tm, U, W, Y, Yb, Zn and Zr.

Of these, the elements As, Br, Cd, Sb and Sn were assigned provisional values, principally because data distributions plotted in Figure 1 possess some degree of asymmetry.

Charts in Figure 2 show distribution data for elements that were not judged to be sufficiently satisfactory in the statistical analysis to assign values. In the present round, values could not be assigned to the following elements/species, despite the availability of sufficient analytical results:

FeO, H_2O^+, CO_2, LOI, B, Bi, Cl, F, Ge, Hg, I, S, Se, W.

Of these, the element/species FeO, CO_2, LOI and W are presented in Figure 2 with guidance values. There is some degree of consensus in results reported for these elements to provide some guidance to contributing laboratories. However, these data must be interpreted with caution.

For other elements that are not included in either of these two lists, insufficient data were reported to allow any assessment to be made.

The most common reasons for elements failing the assessment of assigned values were as follows:

(i) Insufficient number of contributed results.
(ii) Results showing a strong positive skew in the frequency distribution diagram, sometimes with an indication of multi-modality.
(iii) A robust mean clearly different from the mode, which makes the determination of a consensus impracticable.
(iv) A very wide distribution of results as judged by the robust standard deviation value so that no matter where the consensus was placed, most of the participants would receive an 'unsatisfactory' classification if z-scores were calculated.

Z-score analysis

As in previous rounds, laboratories were invited to choose one of two performance standards against which their analytical results would be judged:

Data quality 1 for laboratories working to a 'pure geochemistry' standard of performance, where analytical results are designed for geochemical research and where care is taken to provide data of high precision and accuracy, sometimes at the expense of a reduced sample throughput rate.

Data quality 2 for laboratories working to an 'applied geochemistry' standard of performance, where, although precision and accuracy are still important, the main objective is to provide results on large numbers of samples collected, for example, as part of geochemical mapping projects or geochemical exploration programmes.

The target standard deviation (H_a) for each element assessed was calculated from a modified form of the Horwitz function as follows:

$H_a = k.X_a^{0.8495}$

Where X_a is the concentration of the element expressed as a *fraction*, and the factor k = 0.01 for pure geochemistry labs and k=0.02 for applied geochemistry labs.

Z-scores were calculated for each elemental result submitted by each laboratory from:

$z = [X - X_a] / H_a$

where

X is the contributed result, X_a is the assigned value and H_a is the target standard deviation.

Z-score results are listed in Table 3 and participating laboratories are invited to assess their performance using the following criterion:

Z-score results in the range $-2<z<2$ are considered to be 'satisfactory' (in the sense that no action is called for by the participant). If the z-score for any element falls outside this range, contributing laboratories are advised to examine their procedures to ensure that determinations are not subject to unsuspected analytical bias.

Overall performance

A summary of the overall performance of individual laboratories in this round is plotted in Figure 3 as a multiple z-score chart. In this chart, the z-score performance for each element is distinguished by symbols that make it simple to identify whether the results were satisfactory or gave z-scores that exceeded the action limits. This chart is designed to help individual laboratories to judge their overall performance in this proficiency testing round.

Participation in future rounds

The benefit from proficiency testing arises from regular participation and laboratories are invited to contribute to the GeoPT16 round, the sample for which will be distributed during September 2004.

Acknowledgments

The authors thank Jann Matela and Liz Lomas (OU) for valued assistance with the production of this report. The GeoPT programme is organised on behalf of the International Association of Geoanalysts.

Appendix 2 - GeoPT15 Homogeneity Report

The sample was tested for homogeneity by selecting at random ten packets of the material that had been prepared for distribution. Duplicate test portions from each packet were analysed by WD-XRF at the OU. Data for each element were carefully examined for features that would invalidate or unduly weaken the test for sufficient homogeneity. Elements for which the homogeneity data were thus inadequate were excluded from the analysis. The valid data sets were subjected element by element to one-way analysis of variance to derive a number of statistical parameters from which homogeneity could be assessed. Because of deficiencies in conventional homogeneity testing statistics, that can flag the presence of heterogeneity at a level that is statistically significant but inconsequential for the purposes of the proficiency test, overall conclusions were evaluated against a standard of 'sufficient homogeneity' as evaluated from the Fearn-Thompson test. The test refers to a different null hypothesis, namely $H : \sigma^2_{sam} \leq \sigma^2_{all}$, where σ^2_{all} is the 'allowable' variance, the highest between-sample variance compatible with the nature of the proficiency test. In the GeoPT programme, conclusions from the Fearn-Thompson test are taken as definitive (T Fearn and M Thompson, *Analyst*, 2001, **126**, 1414-1417).

Results from an evaluation of the homogeneity testing data obtained by the XRF analysis of both glass disks (for majors) and powder pellets (for traces) is given in the following two tables, in which only the key parameters are listed. As part of the data evaluation, it was noted that one Cochraine outlier was detected in the major element results, but was eliminated, as allowed under the revised Harmonised Protocol. In addition, a slight trend was detected in the trace element data, and for some elements, the analytical precision was worse than the ideal limit (elements denoted by an '*' in the table below). These discrepancies were judged not to invalidate the Fearn-Thompson statistic nor the overall conclusions of sufficient homogeneity.

X_a=assigned value calculated as the robust mean of submitted data.

H_a=target precision calculated using a modified version of the Horwitz equation for Data quality 1 ($Ha=0.01Xa^{0.8495}$).

sdm=standard deviation of the mean calculated from submitted data using robust statistics.

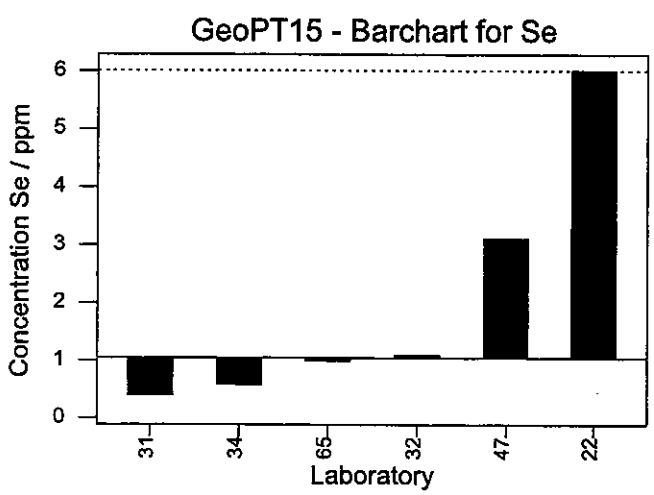

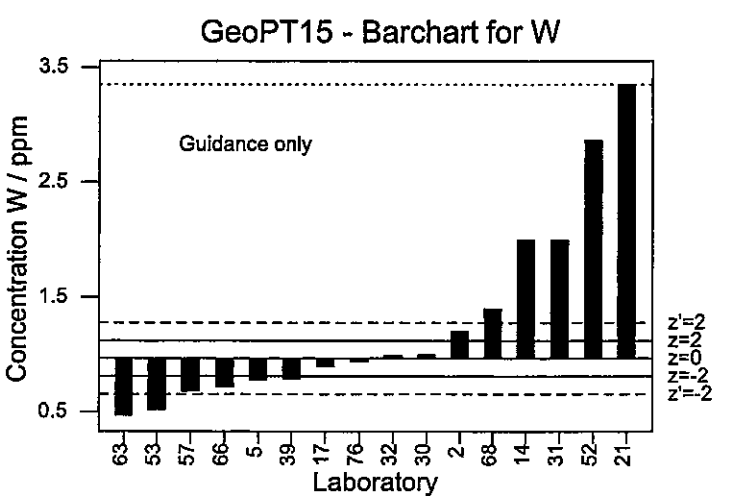

Figure 2 (Part 2). GeoPT15 — MSAN ocean floor sediment: Data distribution charts for elements for which only guidance values can be given or where no value could be assigned.

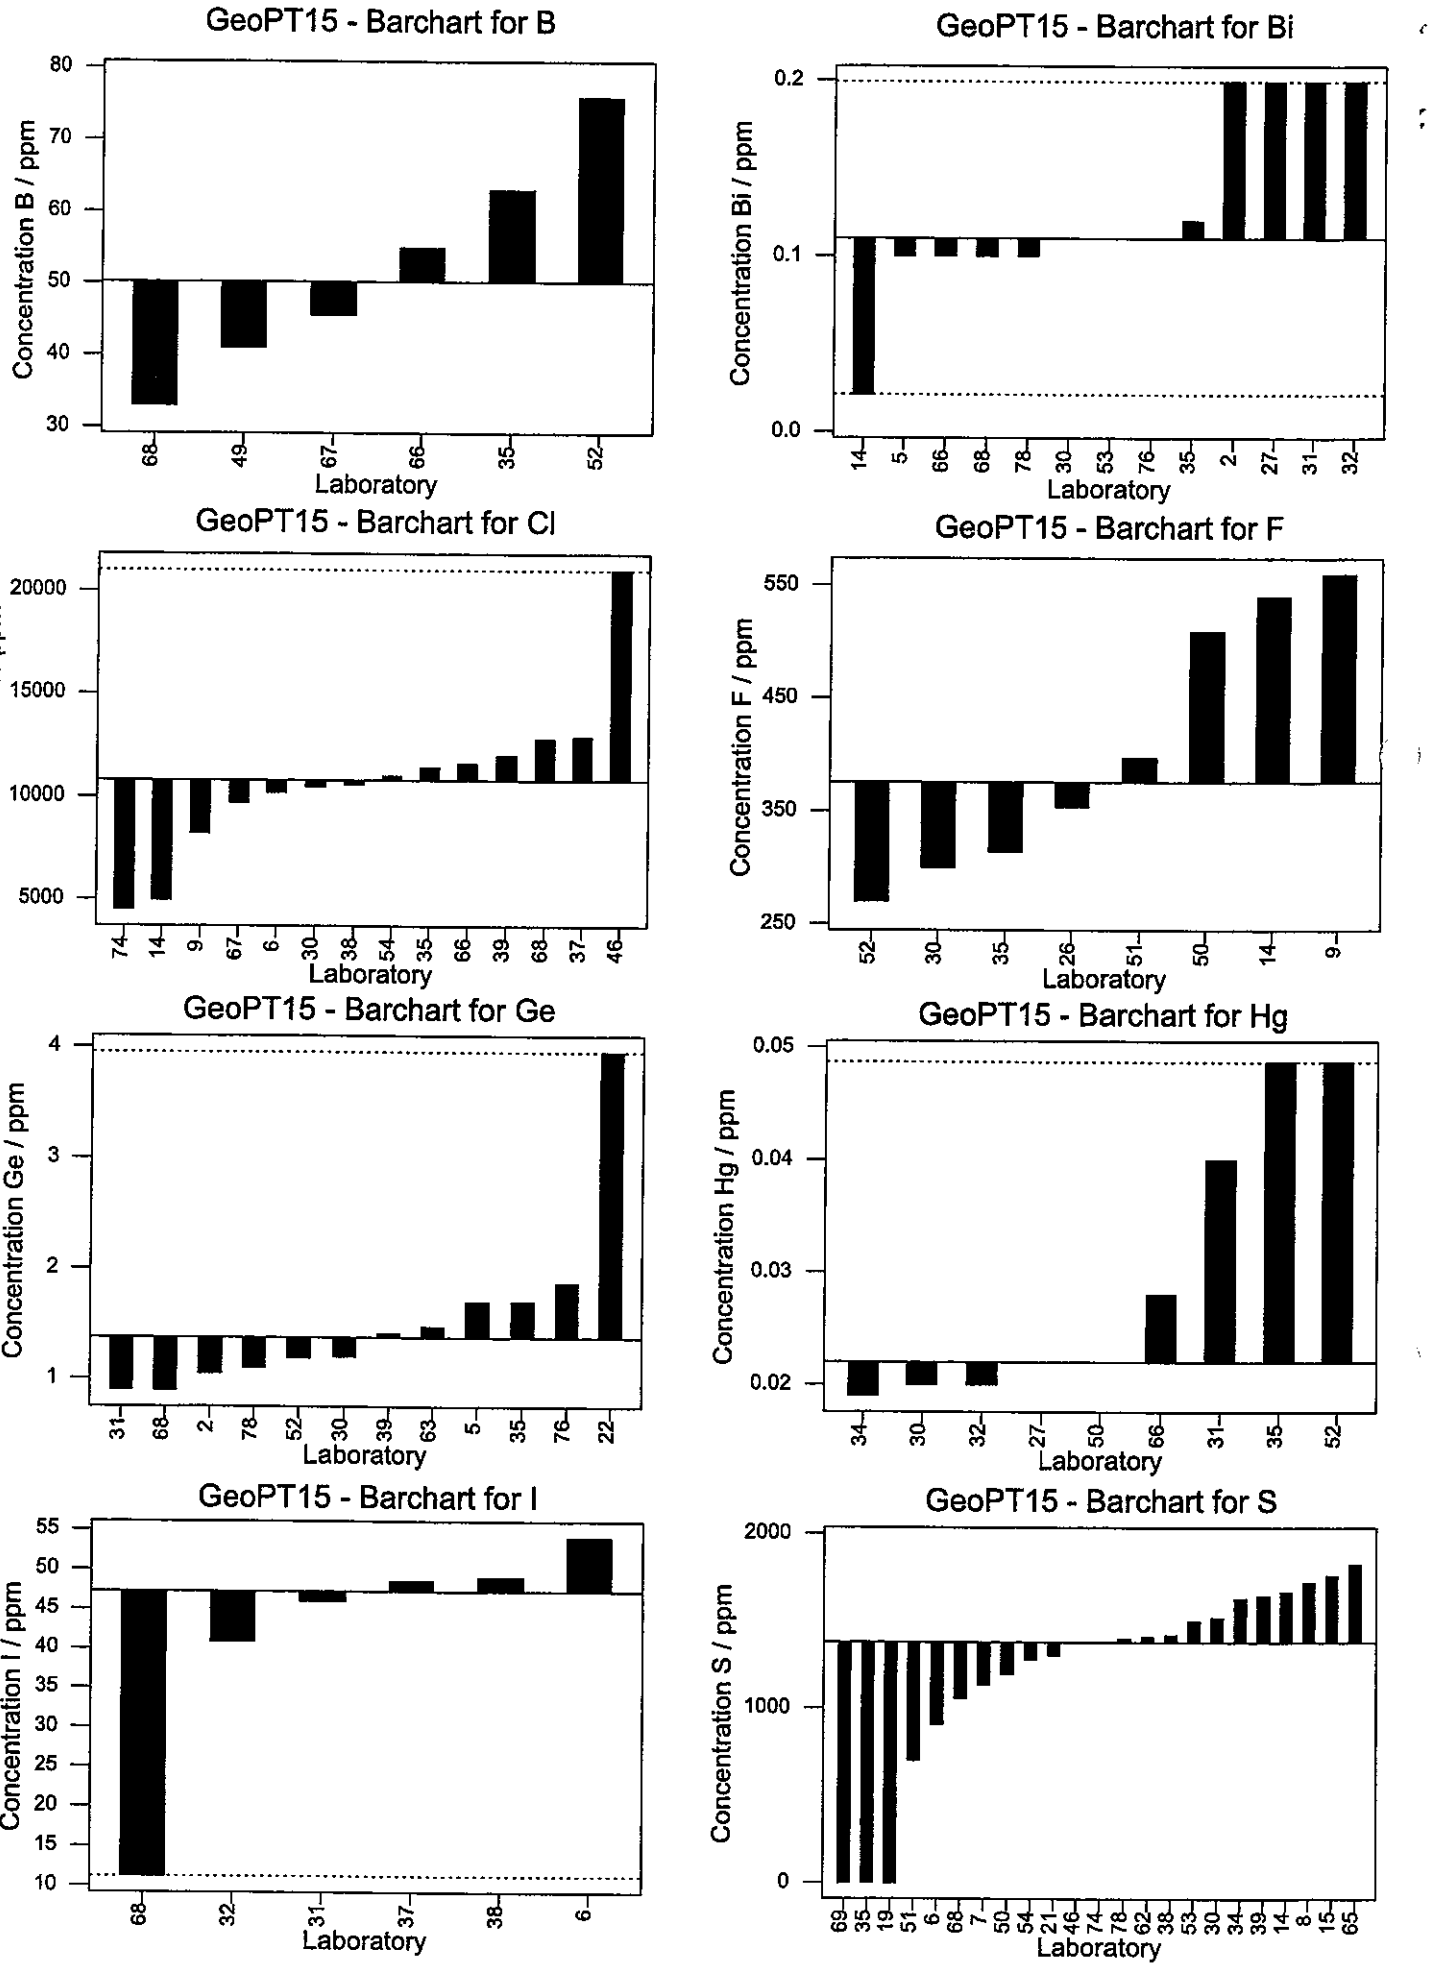

Figure 2 (Part 2). GeoPT14 — MSAN ocean floor sediment: Data distribution charts for elements for which only guidance values can be given or where no value could be assigned.

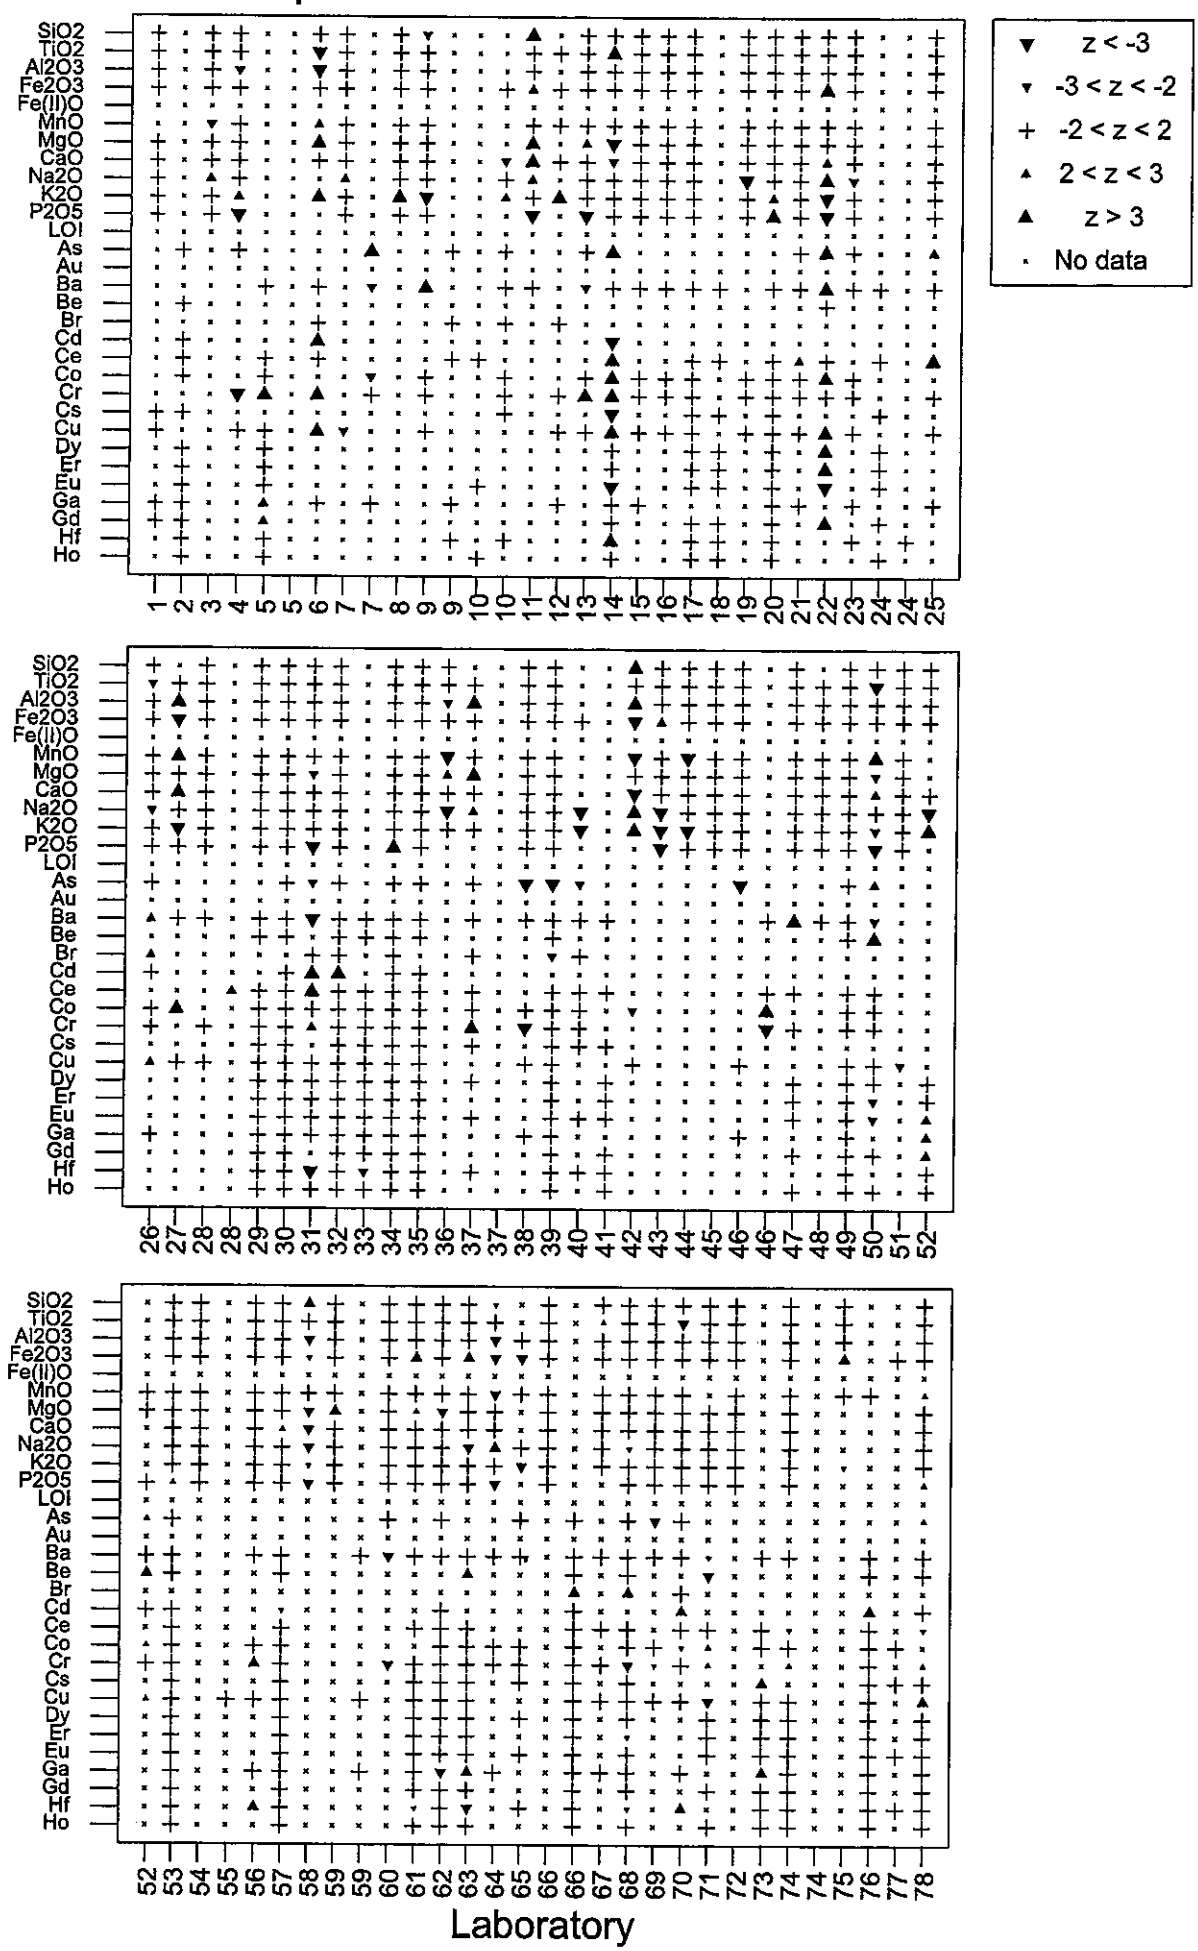

Figure 3 (Part 1) GeoPT15 — MSAN ocean floor sediment: Multiple z-score charts for laboratories participating in the GeoPT15 round. Symbols indicate whether or not an elemental result complies with the -2<z<+2 criteria. Satisfactory data are plotted as '+'. Data for other categories are plotted as follows: z<-3 (▼), -3<z<-2 (▾), +2<z<+3 (▴), z>+3 (▲).

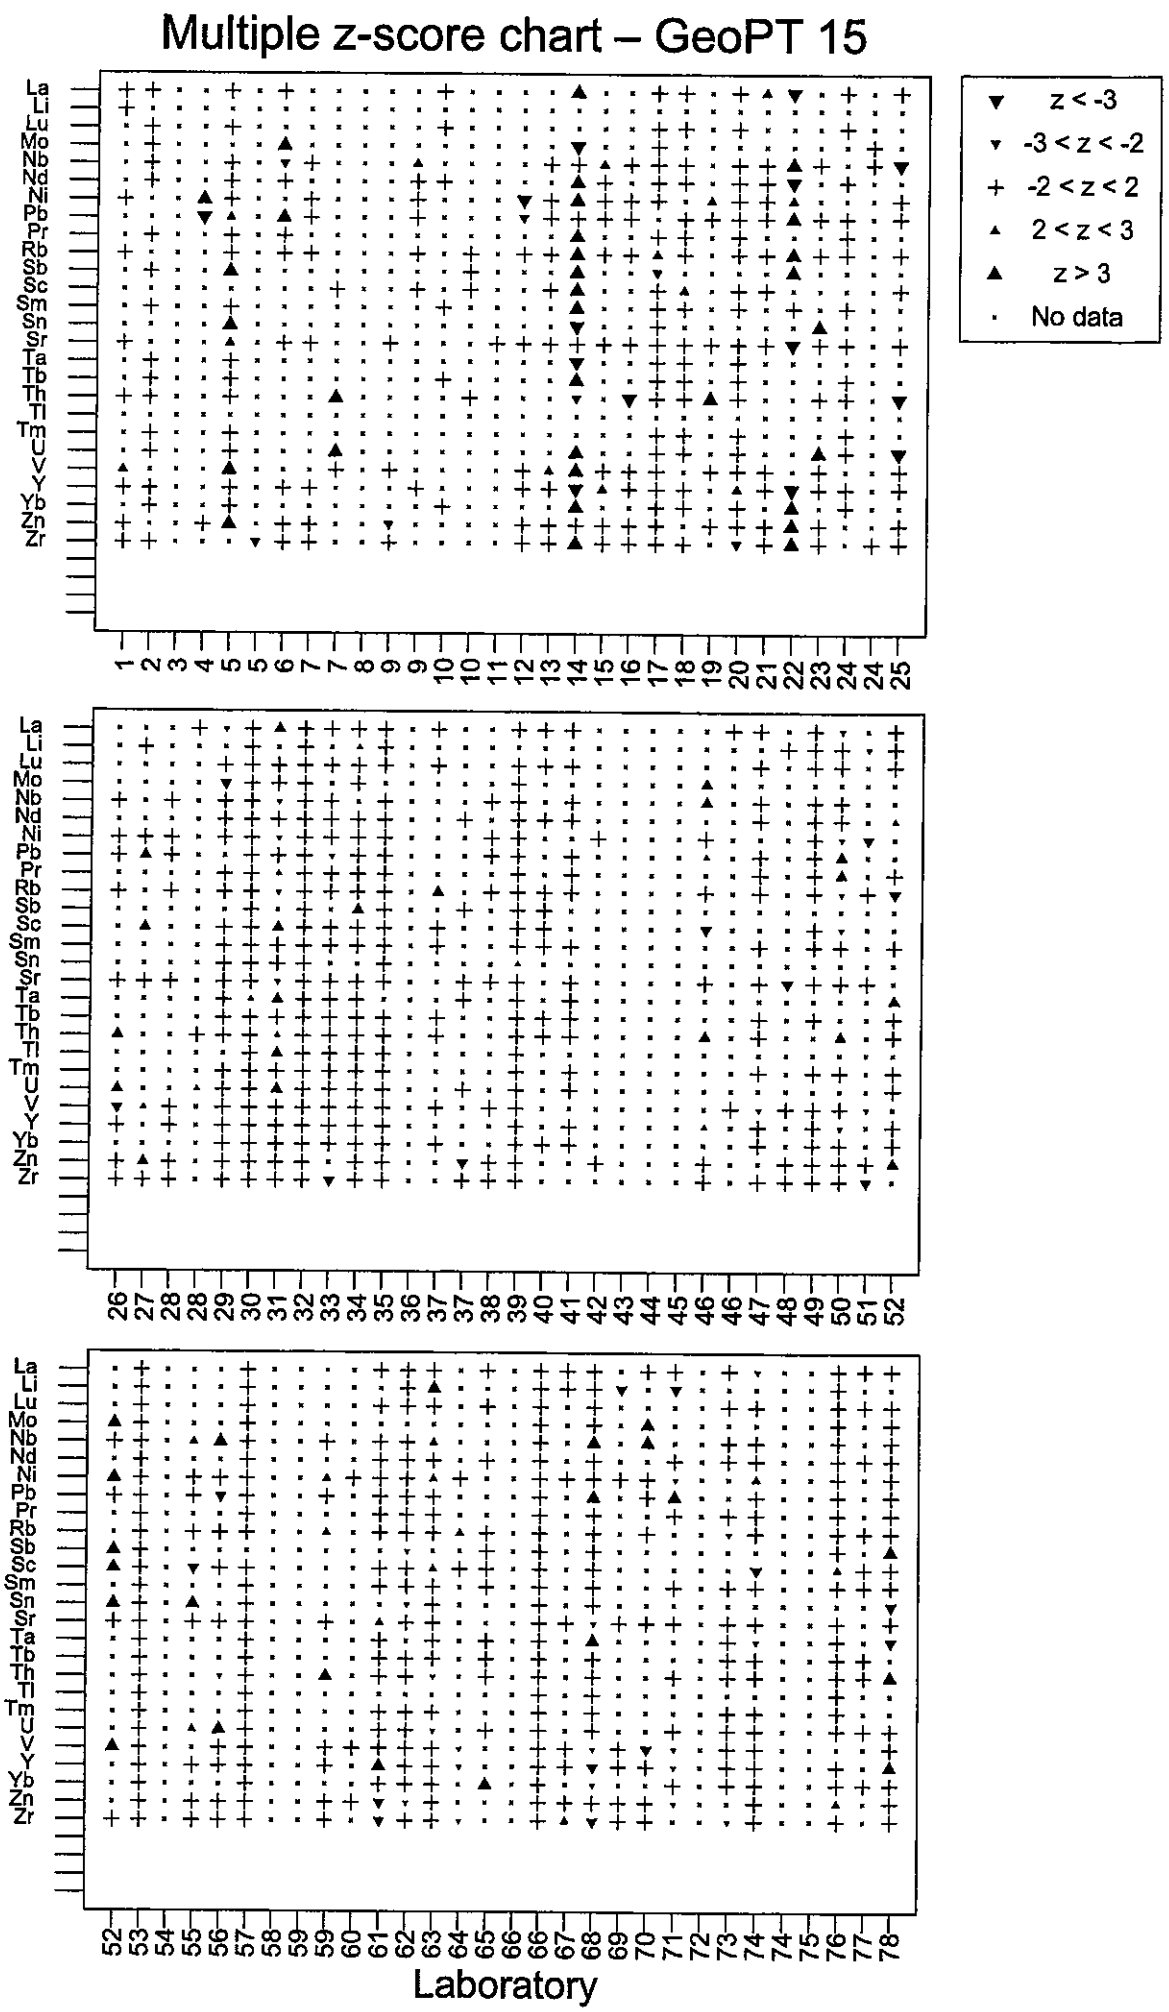

Figure 3 (Part 2) GeoPT15 — MSAN ocean floor sediment: Multiple z-score charts for laboratories participating in the GeoPT15 round. Symbols indicate whether or not an elemental result complies with the -2<z<+2 criteria. Satisfactory data are plotted as '+'. Data for other categories are plotted as follows: z<-3 (▼), -3<z<-2 (▾), +2<z<+3 (▴), z>+3 (▲).
